USER GUIDE

Your computer, in plain words.

Isha is a quiet Windows assistant you summon with a keystroke, tell one thing in ordinary English or Hinglish, and let go. Everything below is what it can do — and the ways people actually use it.

Isha - version 0.5.0

User Guide - July 2026

Runs fully on your PC. Nothing leaves this machine unless you ask.

What Isha is

One surface, summoned on a breath, that holds a single considered thing, acts, and goes still again.

Isha sits silently in your system tray. When you need it, you press a hotkey and a small bar appears in the middle of your screen. You type what you want the way you'd say it to a person — **open chrome, mute, activate study mode** — and Isha does it, shows you one plain line of feedback, and disappears. No menus to hunt through, no syntax to memorise, no window taking up space.

It is deliberately small and calm. It is not a chatbot and not a cloud service: it is a lightweight helper that turns plain instructions into real actions on **your** machine.

Three things that make it different

- **Plain language, including Hinglish.** "chrome kholo", "volume 40 karo" and "open chrome", "set volume to 40" all work. You don't learn commands; you just ask.
- **Modes — the headline feature.** Group the apps and websites you use for an activity, and open or close the whole set with one line. More on this below.
- **Fully local and private.** Isha runs entirely on your PC. It has no account, no sign-in, and sends nothing over the internet unless you explicitly ask it to (for example, to report a problem or check for an update).

Getting started

Install and first run

1. Run the installer (**IshaSetup**). It installs for just you and needs no administrator rights — no scary permission prompt.
2. Isha starts and lives in your **system tray** (the little icons near the clock). Look for the Isha icon.
3. A short first-run welcome explains the hotkey and shows one example. Read it once; it won't appear again.

The one thing to remember: the hotkey

Press **Ctrl + Alt + Space** anywhere, any time, to open the command bar. Type your instruction, press **Enter**, and Isha acts. Press **Escape** to dismiss it without doing anything. You can change this hotkey later in Settings.

Type "help" any time

If you ever forget what you can say, open the bar and type help. Isha shows a one-screen cheat sheet of everything it understands.

Activating your licence (optional)

If you bought Isha, you'll get a licence key by email. Open the bar and type **activate license** followed by your key. Activation happens entirely on your machine — there's nothing to sign into. Isha works the same whether or not it's activated; the licence just supports the project and is used on up to two of your own devices. Type **license status** any time to check.

Four ways to give Isha an instruction

Every path below feeds the same brain, so anything you can type, you can also trigger the other ways — behaviour never changes between them.

Path	How	Best for
The hotkey + bar	Ctrl+Alt+Space, then type	The everyday way — fast and precise
The tray icon	Right-click the tray icon's menu	When your hands are on the mouse
Voice (optional)	A voice hotkey; speak your command	Hands-free; needs an optional add-on
Auto-triggers	Isha acts on time, battery, etc.	Things you want to happen by themselves

The voice and auto-trigger paths are covered in their own sections later. For everyday use, the hotkey is all you need.

Everything you can say

This is the complete vocabulary, grouped by what it touches. You never have to phrase things exactly like this — Isha is forgiving about wording and understands Hinglish — but these show the shape of what's possible.

Apps

Say something like	What happens
open chrome	Launches the app (finds it for you)
close notepad	Closes the app
uninstall <app>	Starts Windows' uninstaller (asks first)

Web

Say something like	What happens
go to youtube	Opens the site in your browser
search python tutorials	Runs a web search for that phrase

System

Say something like	What happens
mute / unmute	Silences or restores your sound
set volume to 50	Sets the volume level
lock screen	Locks your PC
shutdown / restart / sleep / hibernate	Power actions (the big ones ask you to confirm)

Everyday utilities

Say something like	What happens
screenshot	Captures your screen to a file
check disk space	Tells you how full your drive is
check internet	Tells you whether you're online
empty recycle bin	Empties the Recycle Bin
show clipboard history	Shows recent things you've copied
start pomodoro <mode> / stop pomodoro	A focus timer, optionally tied to a mode

Comfort and safety

Say something like	What happens
undo	Reverses your last action
help	Shows the full cheat sheet
alias browser as chrome	Teaches Isha your own word for something
remove alias browser	Forgets that word

Support and licence

Say something like	What happens
report issue <note>	Builds a local report of what went wrong
send report	Sends the most recent report (asks first)
check updates / install update	Checks for and installs a new version (asks first)
activate license <key> / license status / deactivate license	Manage your licence, all offline

Modes — the feature to actually learn

A Mode is a named group of apps and websites you open and close together.

Think about how you start a task. To study, maybe you open Chrome, your notes app, and YouTube, mute distractions, and set your screen to dark. That's five steps, every time. A Mode does all of it in one line.

Create one

```
create study mode chrome and youtube and notion
```

Isha remembers the group under the name **study**.

Use it

Say	What happens
activate study mode	Opens everything in the group at once
deactivate study mode	Closes the whole group back down
update study mode add spotify	Adds an app to the group
update study mode remove youtube	Removes one
delete study mode	Forgets the mode entirely (asks first)

Make a Mode do more than open apps

A Mode can also set your volume, switch your theme, and remember a window layout, so activating it arranges your whole workspace:

Say	What it adds to the mode
study mode vol 20	Sets volume to 20% when the mode activates
study mode theme dark	Switches to dark (or light) theme
study mode layout	Captures where your windows are right now
study mode script <command>	Runs an extra command on activate (off by default — see box)

About mode "scripts" — a deliberately locked door

A mode can hold an extra free-text command to run. Because that is powerful, it is switched OFF by default. To use it you turn on "allow mode scripts" in Settings, and even then Isha shows you the exact command and asks before running it. Automatic triggers will never run a mode script, ever. This is a safety choice, not a limitation to work around.

Auto-triggers — let modes happen by themselves

You can attach a condition to a mode so Isha activates it automatically. Isha checks quietly in the background and acts on the moment the condition becomes true — it never nags and never runs a mode script this way.

Trigger type	Fires when...	Example use
Time	A clock time (optionally on chosen days)	"Work mode" every weekday at 9am
Battery	You unplug and go on battery	"Power saver mode" to dim and quieten
App launch	A certain app starts	"Gaming mode" when Steam opens
Idle	You've been away N minutes	"Away mode" after 10 minutes idle

When an auto-trigger fires, Isha shows a small notification so you always know what changed and why.

The safety nets

Isha is built to be calm even when something goes wrong. A few promises it keeps:

- **It asks before anything drastic.** Shutting down, deleting a mode, uninstalling an app, installing an update — each stops and waits for a clear yes.
- **Undo.** Made a mistake? Type **undo** to reverse your last action.
- **It never pretends.** If something can't be done, Isha tells you plainly why, in one sentence — it never fakes success.
- **It fails safely.** If a piece isn't available on your system, that one thing quietly steps aside and explains itself; the rest keeps working.
- **Nothing leaves your machine unless you ask.** No telemetry, no account, no background uploads. The only times Isha touches the internet are when you tell it to check for an update or send a problem report.

Voice input (optional add-on)

If you'd rather speak, Isha has an optional voice path. Press the voice hotkey (default **Ctrl + Alt + V**), say your command, and it runs through the exact same brain as typing. Voice recognition happens locally too — your speech is not sent to any cloud service.

Voice needs a small add-on (a speech package and a downloaded language model) that isn't included by default, to keep the base app tiny. Until it's set up, Isha simply tells you to use the hotkey or the bar instead — nothing breaks.

Ways people actually use Isha

A few real-world setups to spark ideas. Each is just modes, triggers, and plain commands combined.

The student

A **study mode** opens Chrome, Notion and a lecture playlist, mutes notifications, and goes dark — set to activate on weekdays at 9am. A **break mode** closes it all and opens Spotify. **start pomodoro study** keeps focus sessions honest.

The developer

A **work mode** opens the editor, terminal, docs and the project board, and restores the exact window layout. A **gaming mode** triggered by Steam launching closes work apps and frees up the machine. **undo** quietly fixes the inevitable wrong command.

The focus-seeker

An **idle trigger** flips to a quiet **away mode** after ten minutes. A **battery trigger** drops into **power saver** the moment the laptop is unplugged — dimming and quieting without a thought.

The presenter

A **present mode** closes chat apps, sets volume, switches to light theme and opens the slides — one line before walking on stage, and **deactivate present mode** to put everything back after.

The everyday user

No modes at all — just "mute", "lock screen", "screenshot", "go to gmail", "empty recycle bin" faster than finding each one by hand. Isha is useful from the very first command; modes are there when you want them.

Quick answers

Do I need to be online?

No. Isha runs fully offline. It only reaches the internet if you ask it to check for updates or send a report.

Does it need administrator rights?

No. It installs and runs as just you. That's a deliberate choice for safety and convenience.

Windows warned me the first time I ran it. Is that bad?

On a brand-new app Windows SmartScreen can show a caution until the app builds reputation. Choose to run it if you trust your download source. This is expected for new software, not a sign of a problem.

Where is my data kept?

In your own user folder on this PC. Your modes and settings live in a plain settings file; your licence details (just your name and email) are stored encrypted to your Windows account.

Something didn't work. What now?

Type **report issue** with a short note. Isha builds a local report you can review, and only sends it if you say so with **send report**.
